The process for preparing the starting compound [II] or a salt thereof of the present invention is explained in detail in the following.

Process A

The compound [II] or a salt thereof can be prepared by the fermentation process.

The fermentation process is explained in detail in the following.

The compound [II] or a salt thereof of this invention can be produced by fermentation of the compound [II] or a salt thereof-producing strain belonging to the genus Coleophoma such as Coleophoma sp. F-11899 in a nutrient medium.

(i) Microorganism :

Particulars of the microorganism used for producing the compound [II] or a salt thereof is explained in the following.

The strain F-11899 was originally isolated from a soil sample collected at Iwaki-shi, Fukushima-ken, Japan. This organism grew rather restrictedly on various culture media, and formed dark grey to brownish grey colonies. Anamorph (conidiomata) produced on a steam-sterilized leaf segment affixed on a Miura's LCA plate [1]or a corn meal agar plate by inoculating the isolate, while neither teleomorph nor anamorph formed on the agar media. Its morphological, cultural and physiological characteristics are as follows.

Cultural characteristics on various agar media are summarized in Table 1. Cultures on potato dextrose agar grew rather rapidly, attaining 3.5-4.0 cm in diameter after two weeks at 25° C. This colony surface was plane, felty, somewhat wrinkly and brownish grey. The colony center was pale grey to brownish grey, and covered with aerial hyphae. The reverse color was dark grey. Colonies on malt extract agar grew more restrictedly, attaining 2.5-3.0 cm in diameter under the same conditions. The surface was plane, thin to felty and olive brown. The colony center was yellowish grey, and covered with aerial hyphae. The reverse was brownish grey.

The morphological characteristics were determined on basis of the cultures on a sterilized leaf affixed to a Miura's LCA plate. Conidiomata formed on the leaf segment alone. They were pycnidial, superficial, separate, discoid to ampulliform, flattened at the base, unilocular, thin-walled, black, 90-160(-200) μm in diameter and 40-70 μm high. Ostiole was often single, circular, central, papillate, 10-30 μm in diameter and 10-20 μm high. Conidiophores formed from the lower layer of inner pycnidial walls. They were hyaline, simple or sparingly branched, septate and smooth. Conidiogenous cells were enteroblastic, phialidic, determinate, ampulliform to obpyriform, hyaline, smooth, 5-8 x 4-6 μm, with a collarette. The collarettes were campanulate to cylindrical, and 14-18 x 3-5 μm. Conidia were hyaline, cylindrical, thin-walled, aseptate, smooth and 14-16(-18) x 2-3 μm.

The vegetative hyphae were septate, brown, smooth and branched. The hyphal cells were cylindrical and 2-7 μm thick. The chlamydospores were absent.

The strain F-11899 had a temperature range for growth of 0 to 31° C and an optimum temperature of 23 to 27° C on potato dextrose agar.

The above characteristics indicate that the strain F-11899 belongs to the order Coelomycetes [2), 3), 4)]. Thus, we named the strain "Coelomycetes strain F-11899".

These characteristics were observed after 14 days of incubation at 25°C. The color descriptions were based on the Methuen Handbook of Colour [5].

A culture of Coelomycetes strain F-11899 thus named has been deposited with the Fermentation Research Institute Agency of Industrial Science and Technology (1-3, Higashi 1 chome, Tsukuba-shi, IBARAKI 305 JAPAN) on October 26, 1989 under the number of FERM BP-2635.

After that, however, we have further studied the classification of the strain F-11899, and have found that the strain F-11899 resembled Coleophoma empetri (Rostrup) Petrak 1929 2), 3), 4) belonging to the order Coelomycetes, but differed in some pycnidial characteristics : globose or flattened at the base, immersed, and not papillate.

Considering these characteristics, we classified this strain in more detail and renamed it as "Coleophoma sp. F-11899".

In this connection, we have already taken step to amend the name, "Coelomycetes strain F-11899" to Coleophoma sp. F-11899 with the Fermentation Research Institute Agency of Industrial Science and Technology on September 21, 1990.

(ii) Production of the compound [II] or a salt thereof

The compound [II] or a salt thereof of this invention is produced when the compound [II] or a salt thereof-producing strain belonging to the genus Coleophoma is grown in a nutrient medium containing sources of assimilable carbon and nitrogen under aerobic conditions (e.g. shaking culture, submerged

5) Kornerup, A. and Wanscher, J. H.: Methuen Handbook of Colour (3rd ed.), 252 p., Methuen, London, 1983.

culture, etc.).

The preferred sources of carbon in the nutrient medium are carbohydrates such as glucose, sucrose, starch, fructose or glycerin, or the like.

The preferred sources of nitrogen are yeast extract, peptone, gluten meal, cotton seed flour, soybean meal, corn steep liquor, dried yeast, wheat germ, etc., as well as inorganic and organic nitrogen compounds such as ammonium salts (e.g. ammonium nitrate, ammonium sulfate, ammonium phosphate, etc.), urea or amino acid, or the like.

The carbon and nitrogen sources, though advantageously employed in combination, need not to be used in their pure form because less pure materials, which contain traces of growth factors and considerable quantities of mineral nutrients, are also suitable for use.

When desired, there may be added to the medium mineral salts such as sodium or calcium carbonate, sodium or potassium phosphate, sodium or potassium chloride, sodium or potassium iodide, magnesium salts, copper salts, zinc salt, or cobalt salts, or the like.

If necessary, especially when the culture medium foams seriously a defoaming agent, such as liquid paraffin, fatty oil, plant oil, mineral oil or silicone, or the like may be added.

As in the case of the preferred methods used for the production of other biologically active substances in massive amounts, submerged aerobic cultural conditions are preferred for the production of the compound [II] or a salt thereof in massive amounts.

For the production in small amounts, a shaking or surface culture in a flask or bottle is employed.

Further, when the growth is carried out in large tanks, it is preferable to use the vegetative form of the organism for inoculation in the production tanks in order to avoid growth lag in the process of production of the compound [II] or a salt thereof. Accordingly, it is desirable first to produce a vegetative inoculum of the organism by inoculating a relatively small quantity of culture medium with spores or mycelia of the organism and culturing said inoculated medium, and then to transfer the cultured vegetative inoculum to large tanks. The medium, in which the vegetative inoculum is produced, is substantially the same as or different from the medium utilized for the production of the compound [II] or a salt thereof.

Agitation and aeration of the culture mixture may be accomplished in a variety of ways. Agitation may be provided by a propeller or similar mechanical agitation equipment, by revolving or shaking the fermentor, by various pumping equipment or by the passage of sterile air through the medium. Aeration may be effected by passing sterile air through the fermentation mixture.

The fermentation is usually conducted at a temperature between about 10°C and 40°C, preferably 20°C to 30°C, for a period of about 50 hours to 150 hours, which may be varied according to fermentation conditions and scales.

When the fermentation is completed, the culture broth is then subjected for recovery of the compound [II] or a salt thereof to various procedures conventionally used for recovery and purification of biological active substances, for instance, solvent extraction with an appropriate solvent or a mixture of some solvents, chromatography or recrystallization from an appropriate solvent or a mixture of some solvents, or the like.

According to this invention, in general, the compound [II] or a salt thereof is found both in the cultured mycelia and cultured broth. Accordingly, then the compound [II] or a salt thereof is removed from the whole broth by means of extraction using an appropriate organic solvent such as acetone or ethyl acetate, or a mixture of these solvents, or the like.

The extract is treated by a conventional manner to provide the compound [II] or a salt thereof, for example, the extract is concentrated by evaporation or distillation to a smaller amount and the resulting residue containing active material, i.e. the compound [II] or a salt thereof is purified by conventional purification procedures, for example, chromatography or recrystallization from an appropriate solvent or a mixture of some solvents.

When the object compound is isolated as a salt of the compound [II], it can be converted to the free compound [II] or another salt of the compound [II] according to a conventional manner.

Biological properties of the polypeptide compound [I] of the present invention

In order to show the usefulness of the polypeptide compound [I] of the present invention, some biological data of the representative compounds are explained in the following.

Test 1 Antimicrobial activity (1) :

Antimicrobial activity of the compound of Example 2 disclosed later (hereinafter referred to as FR131535 substance) was measured by micro-broth dilution method in 96 well multi-trays employing yeast

nitrogen base dextrose medium. To a 50 µl sample solution with serial 2-fold dilution was added a 50 µl of microorganism suspension in saline to yield a final concentration of 1 x 10^5 colony forming units/ml. The Candida cultures were incubated at 37° C for 22 hours. After incubation, the growth of microorganism in each well was determined by measuring the turbidity. The results were shown as IC_{50} value in which concentration the turbidity was half of that in the well without sample. The results are shown in Table 2.

Table 2

organism	IC_{50}
Candida albicans FP578	0.31
Candida tropicalis YC118	0.47

Test 2 Acute toxicity of FR131535 substance :

The acute toxicity of the FR131535 substance was determined to ICR mice (female, 4 weeks old) by a single intravenous injection. No toxic symptom was observed at the dose of 500 mg/kg.

Test 3 Antimicrobial activity (2) :

In vitro antimicrobial activity of the compound of Example 12 disclosed later (hereinafter referred to as FR139687 substance) was determined by the two-fold agar-plate dilution method as described below.

One loopful of an overnight culture of each test microorganism in Sabouraud broth containing 2 % Glucose (10^5 viable cells per ml) was streaked on yeast nitrogen base dextrose agar (YNBDA) containing graded concentrations of the FR139687 substance, and the minimal inhibitory concentration (MIC) was expressed in terms of µg/ml after incubation at 30° C for 24 hours.

The pharmaceutical composition of this invention can be used in the form of a pharmaceutical preparation, for example, in solid, semisolid or liquid form, which contains the polypeptide compound [I] or a pharmaceutically acceptable salt thereof, as an active ingredient in admixture with an organic or inorganic carrier or excipient suitable for rectal, pulmonary (nasal or buccal inhalation), nasal, ocular, external (topical), oral or parenteral (including subcutaneous, intravenous and intramuscular) administrations or insufflation. The active ingredient may be compounded, for example, with the usual non-toxic, pharmaceutically acceptable carriers for tablets, pellets, troches, capsules, suppositories, creams, ointments, aerosols, powders for insufflation, solutions, emulsions, suspensions, and any other form suitable for use. And, if necessary, in addition, auxiliary, stabilizing, thickening and coloring agents and perfumes may be used. The polypeptide compound [I] or a pharmaceutical acceptable salt thereof is/are included in the pharmaceutical composition in an amount sufficient to produce the desired antimicrobial effect upon the process or condition of diseases.

For applying the composition to human, it is preferable to apply it by intravenous, intramuscular, pulmonary, or oral administration, or insufflation. While the dosage of therapeutically effective amount of the polypeptide compound [I] varies from and also depends upon the age and condition of each individual patient to be treated, in the case of intravenous administration, a daily dose of 0.01 - 20 mg of the polypeptide compound [I] per kg weight of human being, in the case of intramuscular administration, a daily dose of 0.1 - 20 mg of the polypeptide compound [I] per kg weight of human being, in case of oral administration, a daily dose of 0.5 - 50 mg of the polypeptide compound [I] per kg weight of human being is generally given for treating or preventing infectious diseases.

Preparation 10

(1) A seed medium (160 ml) consisting of sucrose 4%, cotton seed flour 2%, dried yeast 1%, peptone 1%, KH_2PO_4 0.2%, $CaCO_3$ 0.2% and Tween 80 (made by NAKARAI CHEMICALS LTD.) 0.1% was poured into each of two 500 ml Erlenmeyer flasks and sterilized at 121°C for 30 minutes. A loopful of slant culture of Coleophoma sp. F-11899 was inoculated to each of the medium and cultured under shaking condition at 25°C for 4 days.

A production medium (20 liters) consisting of Pine Dex #3 (made by Matsutani Chemical Ltd.) 3%, glucose 1%, wheat germ 1%, cotton seed flour 0.5%, KH_2PO_4 2%, $Na_2HPO_4 \cdot 12H_2O$ 1.5%, $ZnSO_4 \cdot 7H_2O$ 0.001% and Adekanol (defoaming agent, made by Asahi Denka Co., Ltd.) 0.05% was poured into a 30 liter-jar fermentor and sterilized at 121°C for 30 minutes.

The resultant seed culture broth (320 ml) was inoculated to the production medium and cultured at 25°C for 4 days, agitated at 200 rpm and aerated at 20 liters per minute. To the cultured broth thus obtained (20 liters) was added an equal volume of acetone. After occasionally stirring at room temperature for a while, the broth was filtered. The filtrate was concentrated in vacuo to remove acetone. The aqueous filtrate (10 liters) was washed with two equal volume of ethyl acetate and extracted with n-butanol (10 liters) twice. The combined n-butanol layer was concentrated in vacuo and the residue was applied on a column (300 ml) of Silica gel 60 (made by E. Merck) and eluted with a stepwise organic solvent mixture consisting

of dichloromethane-methanol. The fractions having anti-Candida activity were eluted in the range of the solvent mixture (3:1 through 1:1). The active fractions were combined and concentrated in vacuo to dryness. The residue was dissolved in 50% aqueous methanol (15 ml) and applied on a column (250 ml) of ODS YMC GEL (made by Yamamura Chemical Lab.). The column was washed with 50% aqueous methanol and eluted with 80% aqueous methanol. The eluate was concentrated and was further purified on a centrifugal partition chromatography (CPC) using a solvent system n-butanol:methanol:water (4:1:5) of upper stationary phase and lower mobile phase in a descending model. The pooled fractions containing the object compound (major component) were concentrated in vacuo and applied on a column (35 ml) of silica gel 60. The column was developed with n-butanol:acetic acid:water (6:1:1). The active fractions were combined and concentrated in vacuo to dryness and dissolved in a small volume of 50% aqueous methanol. The solution was passed through a column (3.5 ml) of ODS YMC GEL. The column was washed with 50% aqueous methanol and eluted with methanol. The eluate was concentrated to dryness, dissolved in a small volume of water and adjusted to pH 7.0 with 0.01N NaOH. The solution was freeze-dried to give a white powder of said compound in its sodium salt form (hereinafter referred to as FR901379 substance) (11 mg).

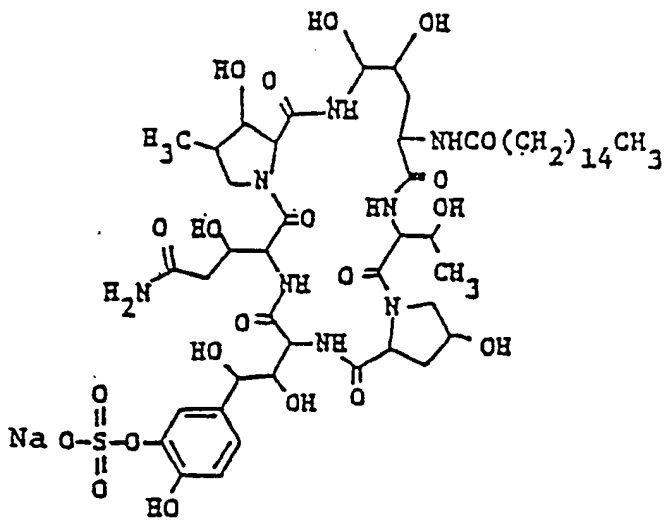
From the analysis of the above physical and chemical properties, and the result of the further investigation of identification of chemical structure, the chemical structure of the FR901379 substance has been identified and assigned as follows.



Example 1

N-acyl group of FR901379 substance was eliminated by the reaction with an enzyme. In the following, this elimination process is explained in detail.

(1) Fermentation of Actinoplanes utahensis

The enzyme which is useful for eliminating N-acyl group of FR901379 Substance is produced by certain microorganisms of the Actinoplanaceae, preferably the microorganism Actinoplanes utahensis IFO-13244.

A stock culture of Actinoplanes utahensis IFO-13244 is prepared and maintained on agar slant. A loopful of the slant culture was inoculated into a seed medium consisted of starch 1%, sucrose 1%, glucose 1%, cotton seed flour 1%, peptone 0.5%, soy bean meal 0.5% and $CaCO_3$ 0.1%. The inoculated vegetative medium was incubated in a 225-ml wide mouth Erlenmeyer flask at 30° C for about 72 hours on a rotary shaker.

This incubated vegetative medium was used directly to inoculate into a production medium consisted of sucrose 2%, peanut powder 1%, K_2HPO_4 0.12% KH_2PO_4 0.05% and $MgSO_4$ $7H_2O$ 0.025%. The inoculated production medium was allowed to ferment in a 30-liter jar fermentor at a temperature of 30° C for about 80 hours. The fermentation medium was stirred with conventional agitators at 250 rpm and aerated at 20 liters per minute. The vegetative mycelium was collected from the fermented broth by filtration and once washed with water. The washed mycelium was directly used to eliminate N-acyl group of FR901379 substance as an enzyme source.

(2) Elimination Condition

FR901379 substance was dissolved in 0.25 M phosphate buffer (pH 6.5) at a concentration of 0.9 mg/ml. To a 36-liter of the solution was added a 2 kg wet weight of washed mycelium of Actinoplanes utahensis IFO-13244. The elimination reaction was carried out at 37° C under for 23 hours. Reduction of FR901379 substance and increase of the deacylated FR901379 substance(hereinafter referred to as FR133303 substance) were measured using a HPLC equipped with a reverse phase column. From a 30 g of FR901379 substance, a 22.2 g of FR133303 substance was formed in the reaction mixture.

(3) Isolation of FR133303 Substance

The reaction mixture described above was filtered with a filter aid. The mycelial cake was discarded. The filtrate thus obtained was passed through a column of activated carbon (2 L). The column was washed with 6 L of water and eluted with 12 L of 50% aqueous acetone. The eluate was evaporated in vacuo to remove acetone and then passed through a column (4 L) of YMC GEL ODS-AM 120-S50 (Yamamura

Chemical Labs). The column was washed with water and eluted with 2% aqueous acetonitrile containing 50 mM NaH_2PO_4. Elution was monitored by analytical HPLC, using a column of LiChrospher 100 RP-18 (Cica-MERCK) and a solvent system of 3% aqueous acetonitrile containing 0.5% $NH_4H_2PO_4$ at a flow rate of 1 ml/min, detecting the FR133303 substance with a UV monitor at 210 nm. The fractions containing the FR133303 substance were combined and passed through a column of activated carbon (400 ml). The column was washed with water and eluted with 50% aqueous acetone. The eluate was concentrated in vacuo to remove acetone and lyophilized to give 16.4 g of FR133303 substance as a white powder.

The fermentation process is explained in detail in the following.

The compound [II] or a salt thereof of this invention can be produced by fermentation of the compound [II] or a salt thereof-producing strain belonging to the genus Coleophoma such as Coleophoma sp. F-11899 in a nutrient medium.

(i) Microorganism :

Particulars of the microorganism used for producing the compound [II] or a salt thereof is explained in the following.

The strain F-11899 was originally isolated from a soil sample collected at Iwaki-shi, Fukushima-ken, Japan. This organism grew rather restrictedly on various culture media, and formed dark grey to brownish grey colonies. Anamorph (conidiomata) produced on a steam-sterilized leaf segment affixed on a Miura's LCA plate[1)] or a corn meal agar plate by inoculating the isolate, while neither teleomorph nor anamorph formed on the agar media. Its morphological, cultural and physiological characteristics are as follows.

Cultural characteristics on various agar media are summarized in Table 1. Cultures on potato dextrose agar grew rather rapidly, attaining 3.5-4.0 cm in diameter after two weeks at 25°C. This colony surface was plane, felty, somewhat wrinkly and brownish grey. The colony center was pale grey to brownish grey, and covered with aerial hyphae. The reverse color was dark grey. Colonies on malt extract agar grew more restrictedly, attaining 2.5-3.0 cm in diameter under the same conditions. The surface was plane, thin to felty and olive brown. The colony center was yellowish grey, and covered with aerial hyphae. The reverse was brownish grey.

The morphological characteristics were determined on basis of the cultures on a sterilized leaf affixed to a Miura's LCA plate. Conidiomata formed on the leaf segment alone. They were pycnidial, superficial, separate, discoid to ampulliform, flattened at the base, unilocular, thin-walled, black, 9.0-160(-200) μm in diameter and 40-70 μm high. Ostiole was often single, circular, central, papillate, 10-30 μm in diameter and 10-20 μm high. Conidiophores formed from the lower layer of inner pycnidial walls. They were hyaline, simple or sparingly branched, septate and smooth. Conidiogenous cells were enteroblastic, phialidic, determinate, ampulliform to obpyriform, hyaline, smooth, 5-8 x 4-6 μm, with a collarette. The collarettes were campanulate to cylindrical, and 14-18 x 3-5 μm. Conidia were hyaline, cylindrical, thin-walled, aseptate, smooth and 14-16(-18) x 2-3 μm.

The vegetative hyphae were septate, brown, smooth and branched. The hyphal cells were cylindrical and 2-7 μm thick. The chlamydospores were absent.

The strain F-11899 had a temperature range for growth of 0 to 31°C and an optimum temperature of 23 to 27°C on potato dextrose agar.

The above characteristics indicate that the strain F-11899 belongs to the order Coelomycetes[2), 3), 4)]. Thus, we named the strain "Coelomycetes strain F-11899".

A culture of Coelomycetes strain F-11899 thus. named has been deposited with the Fermentation Research Institute Agency of Industrial Science and Technology (1-3, Higashi 1 chome, Tsukuba-shi, IBARAKI 305 JAPAN) on October 26, 1989 under the number of FERM BP-2635.

After that, however, we have further studied the classification of the strain F-11899, and have found that the strain F-11899 resembled Coleophoma empetri (Rostrup) Petrak 1929 2), 3), 4) belonging to the order Coelomycetes, but differed in some pycnidial characteristics : globose or flattened at the base, immersed, and not papillate.

Considering these characteristics, we classified this strain in more detail and renamed it as "Coleophoma sp. F-11899".

In this connection, we have already taken step to amend the name, "Coelomycetes strain F-11899" to Coleophoma sp. F-11899 with the Fermentation Research Institute Agency of Industrial Science and Technology on September 21, 1990.

(ii) Production of the compound [II] or a salt thereof

The compound [II] or a salt thereof of this invention is produced when the compound [II] or a salt thereof-producing strain belonging to the genus Coleophoma is grown in a nutrient medium containing sources of assimilable carbon and nitrogen under aerobic conditions (e.g. shaking culture, submerged culture, etc.).

The preferred sources of carbon in the nutrient medium are carbohydrates such as glucose, sucrose, starch, fructose or glycerin, or the like.

The preferred sources of nitrogen are yeast extract, peptone, gluten meal, cotton seed flour, soybean meal, corn steep liquor, dried yeast, wheat germ, etc., as well as inorganic and organic nitrogen compounds such as ammonium salts (e.g. ammonium nitrate, ammonium sulfate, ammonium phosphate, etc.), urea or amino acid, or the like.

The carbon and nitrogen sources, though advantageously employed in combination, need not to be used in their pure form because less pure materials, which contain traces of growth factors and considerable quantities of mineral nutrients, are also suitable for use.

When desired, there may be added to the medium mineral salts such as sodium or calcium carbonate, sodium or potassium phosphate, sodium or potassium chloride, sodium or potassium iodide, magnesium salts, copper salts, zinc salt, or cobalt salts, or the like.

If necessary, especially when the culture medium foams seriously a defoaming agent, such as liquid paraffin, fatty oil, plant oil, mineral oil or silicone, or the like may be added.

As in the case of the preferred methods used for the production of other biologically active substances in massive amounts, submerged aerobic cultural conditions are preferred for the production of the compound [II] or a salt thereof in massive amounts.

For the production in small amounts, a shaking or surface culture in a flask or bottle is employed.

Further, when the growth is carried out in large tanks, it is preferable to use the vegetative form of the organism for inoculation in the production tanks in order to avoid growth lag in the process of production of the compound [II] or a salt thereof. Accordingly, it is desirable first to produce a vegetative inoculum of the organism by inoculating a relatively small quantity of culture medium with spores or mycelia of the organism and culturing said inoculated medium, and then to transfer the cultured vegetative inoculum to large tanks. The medium, in which the vegetative inoculum is produced, is substantially the same as or different from the medium utilized for the production of the compound [II] or a salt thereof.

Agitation and aeration of the culture mixture may be accomplished in a variety of ways. Agitation may be provided by a propeller or similar mechanical agitation equipment, by revolving or shaking the fermentor, by various pumping equipment or by the passage of sterile air through the medium. Aeration may be effected by passing sterile air through the fermentation mixture.

The fermentation is usually conducted at a temperature between about 10°C and 40°C, preferably 20°C to 30°C, for a period of about 50 hours to 150 hours, which may be varied according to fermentation conditions and scales.

When the fermentation is completed, the culture broth is then subjected for recovery of the compound [II] or a salt thereof to various procedures conventionally used for recovery and purification of biological active substances, for instance, solvent extraction with an appropriate solvent or a mixture of some solvents, chromatography or recrystallization from an appropriate solvent or a mixture of some solvents, or the like.

According to this invention, in general, the compound [II] or a salt thereof is found both in the cultured mycelia and cultured broth. Accordingly, then the compound [II] or a salt thereof is removed from the whole broth by means of extraction using an appropriate organic solvent such as acetone or ethyl acetate, or a mixture of these solvents, or the like.

The extract is treated by a conventional manner to provide the compound [II] or a salt thereof, for example, the extract is concentrated by evaporation or distillation to a smaller amount and the resulting residue containing active material, i.e. the compound [II] or a salt thereof is purified by conventional purification procedures, for example, chromatography or recrystallization from an appropriate solvent or a mixture of some solvents.

When the object compound is isolated as a salt of the compound [II], it can be converted to the free compound [II] or another salt of the compound [II] according to a conventional manner.

Biological properties of the polypeptide compound [I] of the present invention

In order to show the usefulness of the polypeptide compound [I] of the present invention, some biological data of the representative compounds are explained in the following.

Test 1 Antimicrobial activity (1) :

Antimicrobial activity of the compound of Example 2 disclosed later (hereinafter referred to as FR131535 substance) was measured by micro-broth dilution method in 96 well multi-trays employing yeast nitrogen base dextrose medium. To a 50 µl sample solution with serial 2-fold dilution was added a 50 µl of microorganism suspension in saline to yield a final concentration of 1 x 10^5 colony forming units/ml. The Candida cultures were incubated at 37°C for 22 hours. After incubation, the growth of microorganism in each well was determined by measuring the turbidity. The results were shown as IC_{50} value in which concentration the turbidity was half of that in the well without sample. The results are shown in Table 2.

Table 2

organism	IC_{50}
Candida albicans FP578	0.31
Candida tropicalis YC118	0.47

Test 2 Acute toxicity of FR131535 substance :

The acute toxicity of the FR131535 substance was determined to ICR mice (female, 4 weeks old) by a single intravenous injection. No toxic symptom was observed at the dose of 500 mg/kg.

Test 3 Antimicrobial activity (2) :

In vitro antimicrobial activity of the compound of Example 12 disclosed later (hereinafter referred to as FR139687 substance) was determined by the two-fold agar-plate dilution method as described below.

One loopful of an overnight culture of each test microorganism in Sabouraud broth containing 2 % Glucose (10^5 viable cells per ml) was streaked on yeast nitrogen base dextrose agar (YNBDA) containing graded concentrations of the FR139687 substance, and the minimal inhibitory concentration (MIC) was expressed in terms of µg/ml after incubation at 30°C for 24 hours.

organism	MIC (µg/ml)
Candida albicans YU-1200	0.05

From the test results, it is realized that the polypeptide compound [I] of the present invention has an anti-microbial activity (especially, antifungal activity).

The pharmaceutical composition of this invention can be used in the form of a pharmaceutical preparation, for example, in solid, semisolid or liquid form, which contains the polypeptide compound [I] or a pharmaceutically acceptable salt thereof, as an active ingredient in admixture with an organic or inorganic carrier or excipient suitable for rectal, pulmonary (nasal or buccal inhalation), nasal, ocular, external (topical), oral or parenteral (including subcutaneous, intravenous and intramuscular) administrations or insufflation. The active ingredient may be compounded, for example, with the usual non-toxic, pharmaceutically acceptable carriers for tablets, pellets, troches, capsules, suppositories, creams, ointments, aerosols, powders for insufflation, solutions, emulsions, suspensions, and any other form suitable for use. And, if necessary, in addition, auxiliary, stabilizing, thickening and coloring agents and perfumes may be used. The polypeptide compound [I] or a pharmaceutical acceptable salt thereof is/are included in the pharmaceutical composition in an amount sufficient to produce the desired antimicrobial effect upon the process or condition of diseases.

For applying the composition to human, it is preferable to apply it by intravenous, intramuscular, pulmonary, or oral administration, or insufflation. While the dosage of therapeutically effective amount of the polypeptide compound [I] varies from and also depends upon the age and condition of each individual patient to be treated, in the case of intravenous administration, a daily dose of 0.01 - 20 mg of the polypeptide compound [I] per kg weight of human being, in the case of intramuscular administration, a daily dose of 0.1 - 20 mg of the polypeptide compound [I] per kg weight of human being, in case of oral administration, a daily dose of 0.5 - 50 mg of the polypeptide compound [I] per kg weight of human being is generally given for treating or preventing infectious diseases.

(1) A seed medium (160 ml) consisting of sucrose 4%, cotton seed flour 2%, dried yeast 1%, peptone 1%, KH_2PO_4 0.2%, $CaCO_3$ 0.2% and Tween 80 (made by NAKARAI CHEMICALS LTD.) 0.1% was poured into each of two 500 ml Erlenmeyer flasks and sterilized at 121°C for 30 minutes. A loopful of slant culture of Coleophoma sp. F-11899 was inoculated to each of the medium and cultured under shaking condition at 25°C for 4 days.

A production medium (20 liters) consisting of Pine Dex #3 (made by Matsutani Chemical Ltd.) 3%, glucose 1%, wheat germ 1%, cotton seed flour 0.5%, KH_2PO_4 2%, $Na_2HPO_4 \cdot 12H_2O$ 1.5%, $ZnSO_4 \cdot 7H_2O$ 0.001% and Adekanol (defoaming agent, made by Asahi Denka Co., Ltd.) 0.05% was poured into a 30 liter-jar fermentor and sterilized at 121°C for 30 minutes.

The resultant seed culture broth (320 ml) was inoculated to the production medium and cultured at 25°C for 4 days, agitated at 200 rpm and aerated at 20 liters per minute. To the cultured broth thus obtained (20 liters) was added an equal volume of acetone. After occasionally stirring at room temperature for a while, the broth was filtered. The filtrate was concentrated in vacuo to remove acetone. The aqueous filtrate (10 liters) was washed with two equal volume of ethyl acetate and extracted with n-butanol (10 liters) twice. The combined n-butanol layer was concentrated in vacuo and the residue was applied on a column (300 ml) of Silica gel 60 (made by E. Merck) and eluted with a stepwise organic solvent mixture consisting of dichloromethane-methanol. The fractions having anti-Candida activity were eluted in the range of the solvent mixture (3:1 through 1:1). The active fractions were combined and concentrated in vacuo to dryness. The residue was dissolved in 50% aqueous methanol (15 ml) and applied on a column (250 ml) of ODS YMC GEL (made by Yamamura Chemical Lab.). The column was washed with 50% aqueous methanol and eluted with 80% aqueous methanol. The eluate was concentrated and was further purified on a centrifugal partition chromatography (CPC) using a solvent system n-butanol:methanol:water (4:1:5) of upper stationary phase and lower mobile phase in a descending model. The pooled fractions containing the object compound (major component) were concentrated in vacuo and applied on a column (35 ml) of silica gel 60. The column was developed with n-butanol:acetic acid:water (6:1:1). The active fractions were combined and concentrated in vacuo to dryness and dissolved in a small volume of 50% aqueous methanol. The solution was passed through a column (3.5 ml) of ODS YMC GEL. The column was

washed with 50% aqueous methanol and eluted with methanol. The eluate was concentrated to dryness, dissolved in a small volume of water and adjusted to pH 7.0 with 0.01N NaOH. The solution was freeze-dried to give a white powder of said compound in its sodium salt form (hereinafter referred to as FR901379 substance) (11 mg).

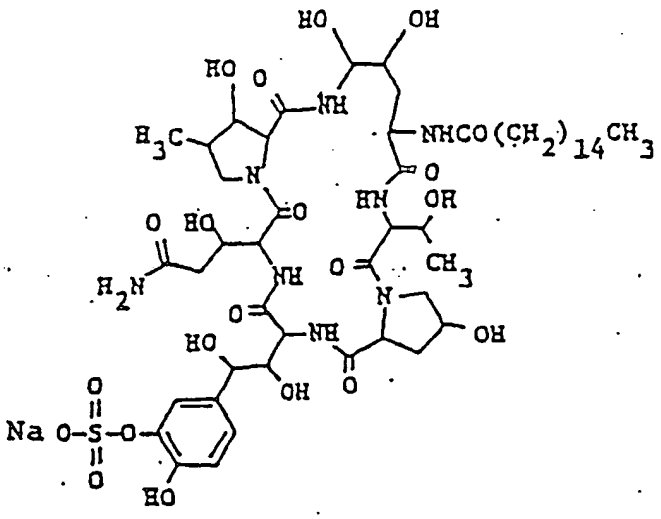
From the analysis of the above physical and chemical properties, and the result of the further investigation of identification of chemical structure, the chemical structure of the FR901379 substance has been identified and assigned as follows.



Example 1

N-acyl group of FR901379 substance was eliminated by the reaction with an enzyme. In the following, this elimination process is explained in detail.

(1) Fermentation of Actinoplanes utahensis

The enzyme which is useful for eliminating N-acyl group of FR901379 substance is produced by certain microorganisms of the Actinoplanaceae, preferably the microorganism Actinoplanes utahensis IFO-13244.

A stock culture of Actinoplanes utahensis IFO-13244 is prepared and maintained on agar slant. A loopful of the slant culture was inoculated into a seed medium consisted of starch 1%, sucrose 1%, glucose 1%, cotton seed flour 1%, peptone 0-5%, soy bean meal 0.5% and $CaCO_3$ 0.1%. The inoculated vegetative medium was incubated in a 225-ml wide mouth Erlenmeyer flask at 30°C for about 72 hours on a rotary shaker.

This incubated vegetative medium was used directly to inoculate into a production medium consisted of sucrose 2%, peanut powder 1%, K_2HPO_4 0.12% KH_2PO_4 0.05% and $MgsO_4$ $7H_2O$ 0.025%. The inoculated production medium was allowed to ferment in a 30-liter jar fermentor at a temperature of 30°C for about 80 hours. The fermentation medium was stirred with conventional agitators at 250 rpm and aerated at 20 liters per minute. The vegetative mycelium was collected from the fermented broth by filtration and once washed with water. The washed mycelium was directly used to eliminate N-acyl group of FR901379 substance as an enzyme source.

(2) Elimination Condition

FR901379 substance was dissolved in 0.25 M phosphate buffer (pH 6.5) at a concentration of 0.9 mg/ml. To a 36-liter of the solution was added a 2 kg wet weight of washed mycelium of Actinoplanes utahensis IFO-13244. The

elimination reaction was carried out at 37°C under for 23 hours. Reduction of FR901379 substance and increase of the deacylated FR901379 substance(hereinafter referred to as FR1333.03 substance) were measured using a HELC equipped with a reverse phase column. From a 30 g of FR901379 substance, a 22.2 g of FR133303 substance was formed in the reaction mixture.

(3) Isolation of FR133303 Substance

The reaction mixture described above was filtered with a filter aid. The mycelial cake was discarded. The filtrate thus obtained was passed through a column of activated carbon (2 L). The column was washed with 6 L of water and eluted with 12 L of 50% aqueous acetone. The eluate was evaporated in vacuo to remove acetone and then passed through a column (4 L) of YMC GEL ODS-AM 120-S50 (Yamamura Chemical Labs). The column was washed with water and eluted with 2% aqueous acetonitrile containing 50 mM NaH_2PO_4. Elution was monitored by analytical HPLC, using a column of Lichrospher 100 RE-18 (Cica-MERCK) and a solvent system of 3% aqueous acetonitrile containing 0.5% $NB_4H_2PO_4$ at a flow rate of 1 ml/min, detecting the FR133303 substance with a UV monitor at 210 nm. The fractions containing the FR133303 substance were combined and passed through a column of activated carbon (400 ml). The column was washed with water and eluted with 50%. aqueous acetone. The eluate was concentrated in vacuo to remove acetone and lyophilized to give 16.4 g of FR133303 substance as a white powder.

Example 2

(1) A solution of 4-hydroxybenzoic acid (19.2 g) in 10% NaOH (120 ml) was dropwise added to 480 ml of dimethyl sulfoxide over 30 minutes during which the temperature in reaction mixture was controlled between 30 and 40°C. After adding, the solution was cooled to 17-20°C. 1-Bromooctane (28.95 g) was dropwise added to the solution over 30 minutes and the reaction mixture was vigorously stirred for 4 hours at room temperature. The reaction mixture was poured into ice water (1200 ml) and acidified with 40 ml of conc. hydrochloric acid. After vigorously stirring for another 1 hour, the resulting solid was removed by filtration and dissolved in 60 ml of acetonitrile. The solution was refluxed over 30 minutes and was allowed to stand overnight at room temperature to yield 4-octyloxybenzoic acid (13.8 g) as a crystal (MP 96°C, Anal Calcd. for $C_{15}H_{22}O_3$: C 71.97, H 8.86, Found : C 71.30, H 8.89).

To a solution of 4-octyloxybenzoic acid (13.8 g) in diethyl ether (552 ml) were added 2,4,5-trichlorophenol (10.87 g) and N,N'-dicyclohexylcarbodiimide (11.37 g). The solution was stirred under a nitrogen atmosphere for 18 hours at room temperature. The precipitate was removed by filtration and the filtrate was concentrated in vacuo.

The residue was dissolved in petroleum ether and was allowed to stand on ice-water. The resulting crystals (15.2 g) were filtered and dissolved in warm n-hexane (150 ml). After standing overnight at room temperature, the resulting crystal was removed by filtration. The filtrate was concentrated to an oil which was purified by a column chromatography over silica gel using a mixture of ethyl acetate and n-hexane to give 2,4,5-trichlorophenyl 4-octyloxybenzoate (7.58 g)(MP 53°C, Anal Calcd. for $C_{21}H_{23}O_3Cl_3$: Cl 24.75, Found : Cl 24.05).

(2) To a solution of FR133303 substance (2.04 g) in N,N-dimethylformamide (60 ml) were added 2,4,5-trichlorophenyl 4-octyloxybenzoate (2.04 g) and 4-dimethylaminopyridine (0.283 g). The solution was stirred under a nitrogen atmosphere at room temperature for 15 hours. 4-Dimethylaminopyridine (0.20 g) was added to the solution and mixture was stirred for another 24 hours. The reaction mixture was poured into water (600 ml) and the pH was adjusted to 6.0. The mixture was washed twice with an equal volume of ethyl acetate and concentrated to 30 ml. The concentrate was applied on a column (150 ml) of DEAE-Toyopearl (Cl type, manufactured by Tosoh). The column was washed with 50% aqueous methanol and developed with 50% aqueous methanol containing 1M sodium chloride aqueous solution. The elution of product was assessed by the same HPLC system as described in Example 1(3) except that the concentration of acetonitrile in solvent was 40%. The fractions containing the object compound were pooled and evaporated in vacuo to remove methanol. The solution was absorbed on a column (1 L) of YMC GEL ODS-AM 120-S50 in order to remove salt. The column was washed with water and eluted with 30% aqueous acetonitrile. The eluate was evaporated in vacuo to remove acetonitrile and lyophylized to give the object compound (hereinafter referred to as FR131535 substance) (1.4 g) as a white powder.

To a solution of octyl phenyl ether (1.53 g) in chloroform (6 ml) was added chlorosulfonic acid at 0°C. The mixture was stirred at room temperature for 30 minutes, then the mixture was poured into a mixture of water and tetrahydrofuran.

The separated organic layer was washed with sodium chloride aqueous solution, dried over magnesium sulfate and then the solvent was evaporated in vacuo. The residue was subjected to a column chromatography on silica gel to give 4-octyloxyphenylsulfonyl chloride (1.25 g).
